

AI Usage Context

Academy Playlists API — supporting document

This document lists the AI tools used while building the Academy Playlists API, what each one was used for, and links to the full conversations where available.

1. ChatGPT — Main Conversation

Used at the start of the project to understand the assignment and scaffold the ASP.NET Core / EF Core backend structure: models, DbContext, initial project layout, and general direction.

2. ChatGPT — Final, Polished Pass

A follow-up conversation used to refine the output of the first chat into the final working implementation — focused on the Repository pattern, controller design, and cleaning up the code that shipped in the repo.

3. GitHub Copilot

Copilot was used inline in the editor for day-to-day debugging and autocomplete-style suggestions while writing code. It doesn't produce a shareable conversation log the way a chat tool does, so no link is available for this part of the work — it's included here for completeness.

4. Note on Usage

All AI-suggested code was reviewed manually, adapted where needed, built, and tested through Swagger before being kept in the final submission. AI was used as a learning and debugging aid rather than as a substitute for understanding the code.
